# The Dilemma between Deduplication and Locality: Can Both be Achieved? 

Xiangyu Zou ${ }^{1}$, Jingsong Yuan ${ }^{1}$, Philip Shilane ${ }^{2}$, Wen Xia ${ }^{1,3}$, Haijun Zhang ${ }^{1}$, and Xuan Wang ${ }^{1}$
${ }^{1}$ Harbin Institute of Technology, Shenzhen; ${ }^{2}$ Dell Technologies

## Background

- Data Deduplication
- Several steps
- Container-based I/O
- Backup storage
- Achieving about 10X-30X deduplication ratio
- Workload: successive snapshots of the primary data
- Deduplication \& Locality
- Common chunks are shared
- Locality of backups is broken

## Background

- Fragmentation problem
- Read amplification
- Random access
- Garbage collection

## Related Work

- Rewrite techniques
- Rewrite some duplicates according to their 'fragmentation degree' to maintain a level of data locality
- CBR(Kaczmarczyk@SYSTOR'12)
- Capping(Lillibridfe@FAST'13)
- HAR(Fu@ATC'14)
- Fragment problem is alleviated with huge cost
- Read amplification remains 2X - 4X
- Deduplication ratio is sacrificed ( $10 \% \sim 40 \%$ )

## Observation \& Motivation

- How read amplification is generated?
- Container-based I/O
- Layout of chunks is the key issue
- Chunks in containers have different lifecycles

## Observation \& Motivation

- How read amplification is generated?
- Container-based I/O
- Layout of chunks is the key issue
- Chunks in containers have different lifecycles

## Observation \& Motivation

- How read amplification is generated?
- Container-based I/O
- Layout of chunks is the key issue
- Chunks in containers have different lifecycles
- How to avoid read amplification?
- Chunks in containers have the same lifecycle
- Classifying chunks with their lifecycle into categories
- Each category maps to a container

## Observation \& Motivation

- How read amplification is generated?
- Container-based I/O
- Layout of chunks is the key issue
- Chunks in containers have different lifecycles
- How to avoid read amplification?
- Chunks in containers have the same lifecycle
- Classifying chunks with their lifecycle into categories
- Each category maps to a container
- But...
- The amount of categories will be very large!!
- Up to $2^{n}-1$, unacceptable ( n is the number

Container1
 of backups)

## Observation \& Motivation

- How to reduce the number of categories.
- We denote four kinds of chunks in a backup version $B_{i}$ as follows:
- Internal duplicate chunks: exist identical chunks in Bi .
- Adjacent duplicate chunks: exist identical chunks in Bi-1.
- Skip duplicate chunks: exist identical chunks in Bi-2, Bi-3, or ....
- Unique chunks: no identical chunks.
- Avoiding deduplicating Skip chunks slightly impacts deduplication ratio.
- The number of categories will be reduced to $n(n+1) / 2$.

Figure 2: Distribution of four kinds of chunks on four backup datasets. Skip duplicate chunks are the least common.

## Remaining Challenges

- We create a feasible chunk layout of deduplicated data with no read amplification.
- How to acquire and keep this kind of chunk layout?
- Reorganizing all chunks after each backup written is costly.
- Mathematical-induction-like approach is considered.

## Our approach

- Our approach implements iterative evolution of our classification-based chunk layout.
- Two techniques
- Neighbor-Duplicate-Focus indexing
- Across-Version-Aware Reorganization
- No read amplification in restoring
- Completely eliminates garbage collection (mark-sweep)

- FIFO deletion: simply delete the earliest category
- Out-of-order deletion
- Truncating corresponding Volume to remove the category which storing unique chunks of Backup $k$

## Evaluations

- Storage is divided into backup space (HDD) and user space (SSD).
- Tested datasets are backed up from the user space to the backup space version by version while the restore runs in the reverse direction.
- Retaining the most recent 20 versions.

Table 1: Four backup datasets used in evaluation.

| Name | Total Size <br> Before Dedup | Versions | Workload Descriptions |
| :---: | :---: | :---: | :---: |
| WEB | 269 GB | 100 | Backup snapshots of website: news.sina.com, <br> captured from June to September in 2016. |
| CHM | 279 GB | 100 | Source codes of Chromium project <br> from v82.0.4066 to v85.0.4165 |
| VMS | 1.55 TB | 100 | Backups of an Ubuntu 12.04 Virtual Machine |
| SYN | 1.38 TB | 200 | Synthetic backups by simulating file <br> create/delete/modify operations [36] |

## Evaluations: Actual Deduplication Ratio

- Actual Deduplication Ratio is defined as $\frac{\text { Total Size of the Dataset }}{\text { Size after Running an Approach }}$
- The storage cost of rewriting techniques, not perfect garbage collections, and other issues are considered.
- CMA means the laziest GC strategy, and PGC means the greediest GC strategy, and they give two kinds of extreme impacts of GC.

(a) WEB

(b) CHM

(c) VMS

(d) SYN

Figure 7: Actual Deduplication Ratio of MFDedup and five approaches running on four datasets (retaining 20 backups).

## Evaluations:Restore Performance (Metric)

- Speed factor is not feasible, we extend it to two metrics
- Seek Factor
- Read Amplification Factor
- MFDedup's Seek Factor is always to be 20.
- The number of retained backup versions.
- Because of internal duplicate chunks, MFDedup's Read Amplification Factor could be smaller than 1.

(a) WEB

(b) VMS

(a) WEB

(b) VMS

## Evaluations:Restore Performance(Speed)

- fread() denotes sequential throughput of the backup device.
- According to the share of internal chunks in datasets, MFDedup nearly completely utilize the performance of storage devices
