

Taming a beast

Improving the Reliability of a Monolithic Web Service

Syed Humza Shah

Senior Software Engineer, Deliveroo

Scenario 1: Web clients reach the same service

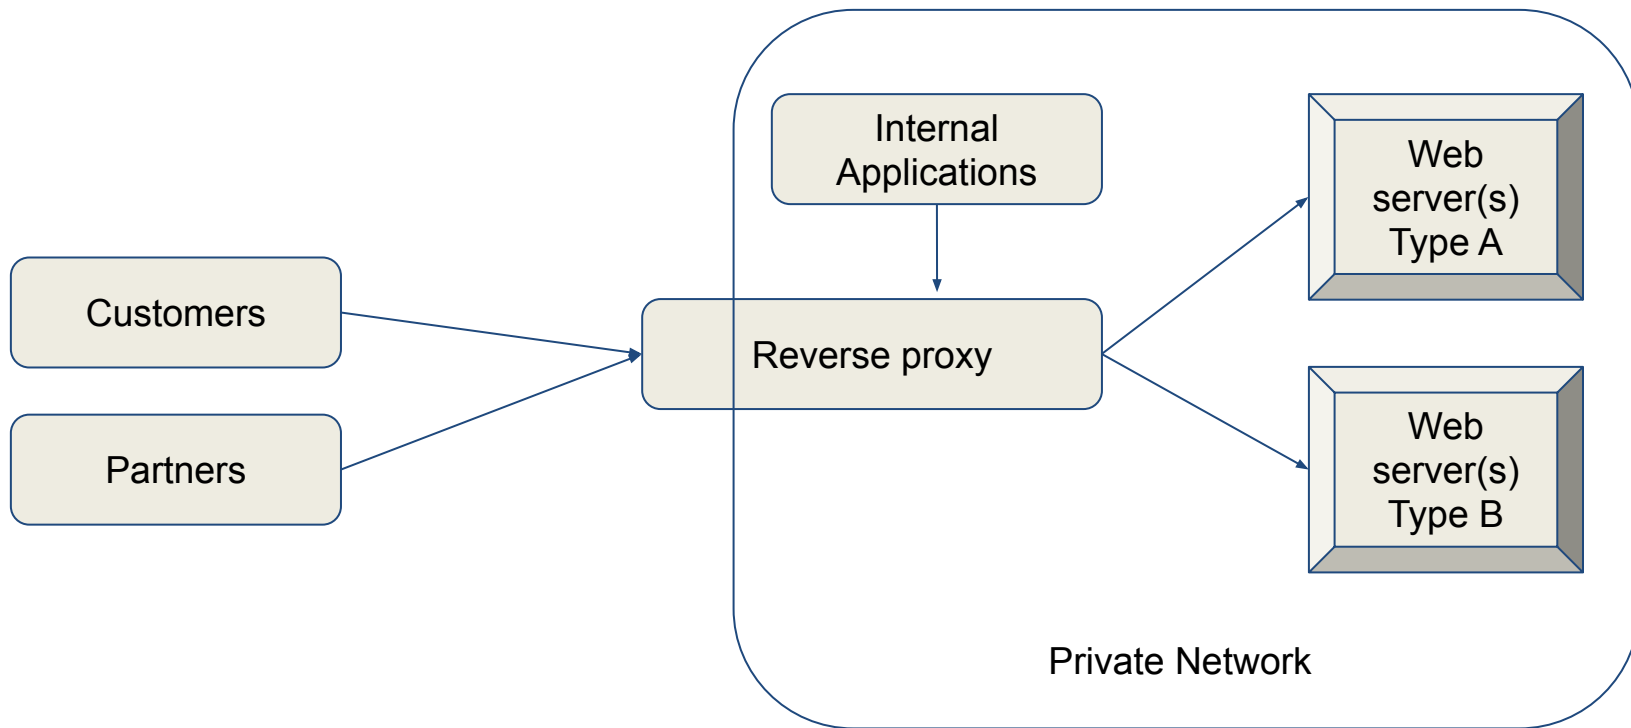

Scenario 1: Problems

- All web servers have the same resources
- CDN downtime affects all web clients
- Internal API services face needless latency
- Difficult root cause identification
- Specific faulty workloads can affect all clients

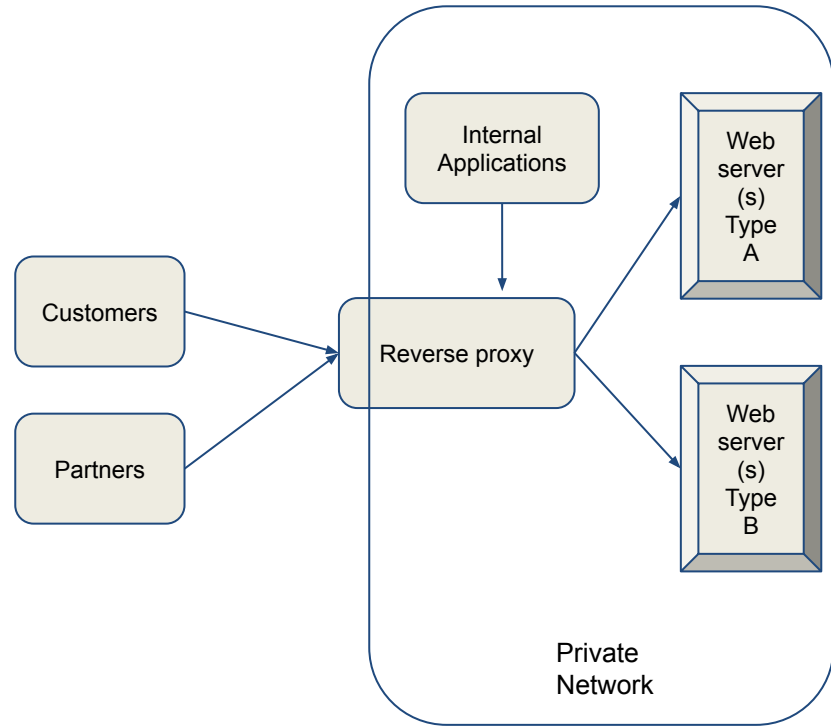

Recipe 1: Separate external/internal web clients

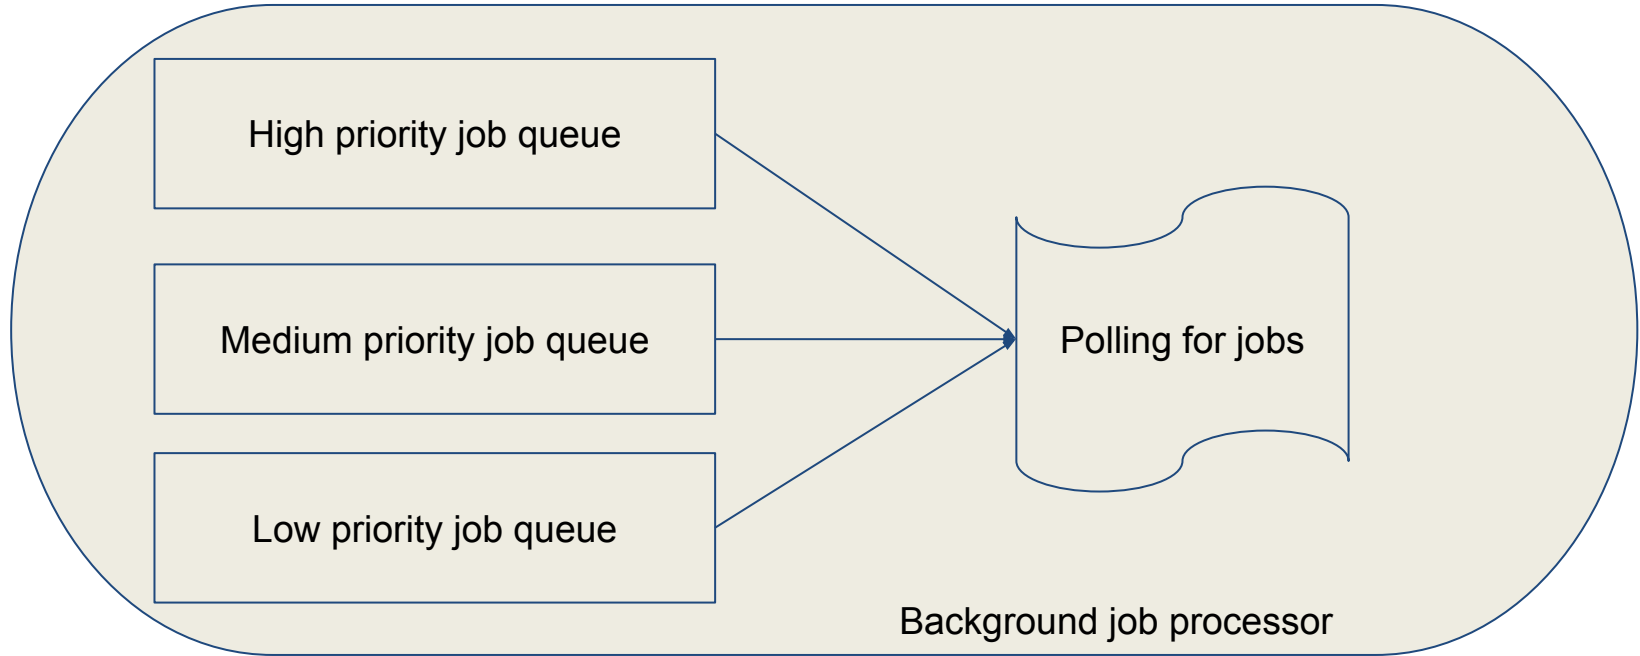

Recipe 1: Improvements

- Better resource utilisation
- Separate public/internal traffic
- Faulty workloads are scoped
- Reverse proxy gives us faster levers

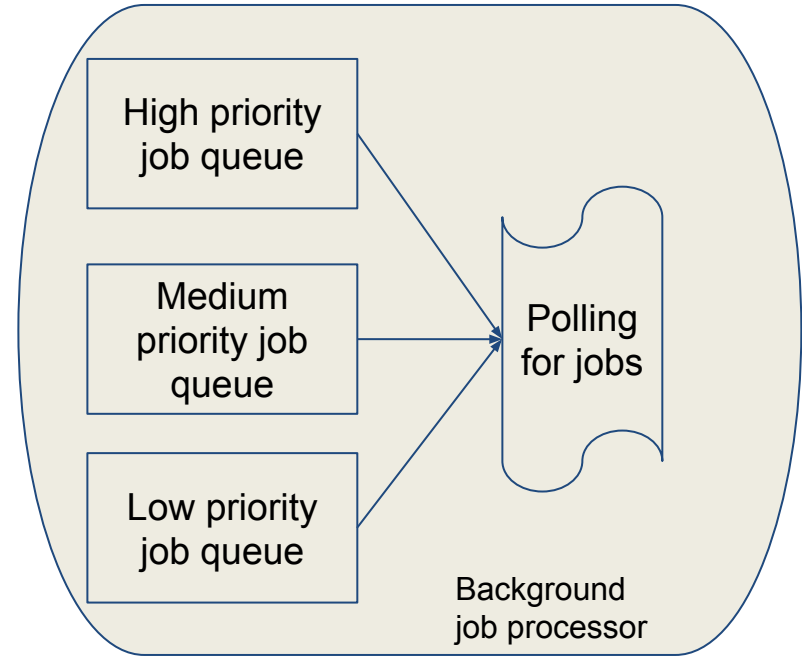

Scenario 2: Job worker processes multiple queues

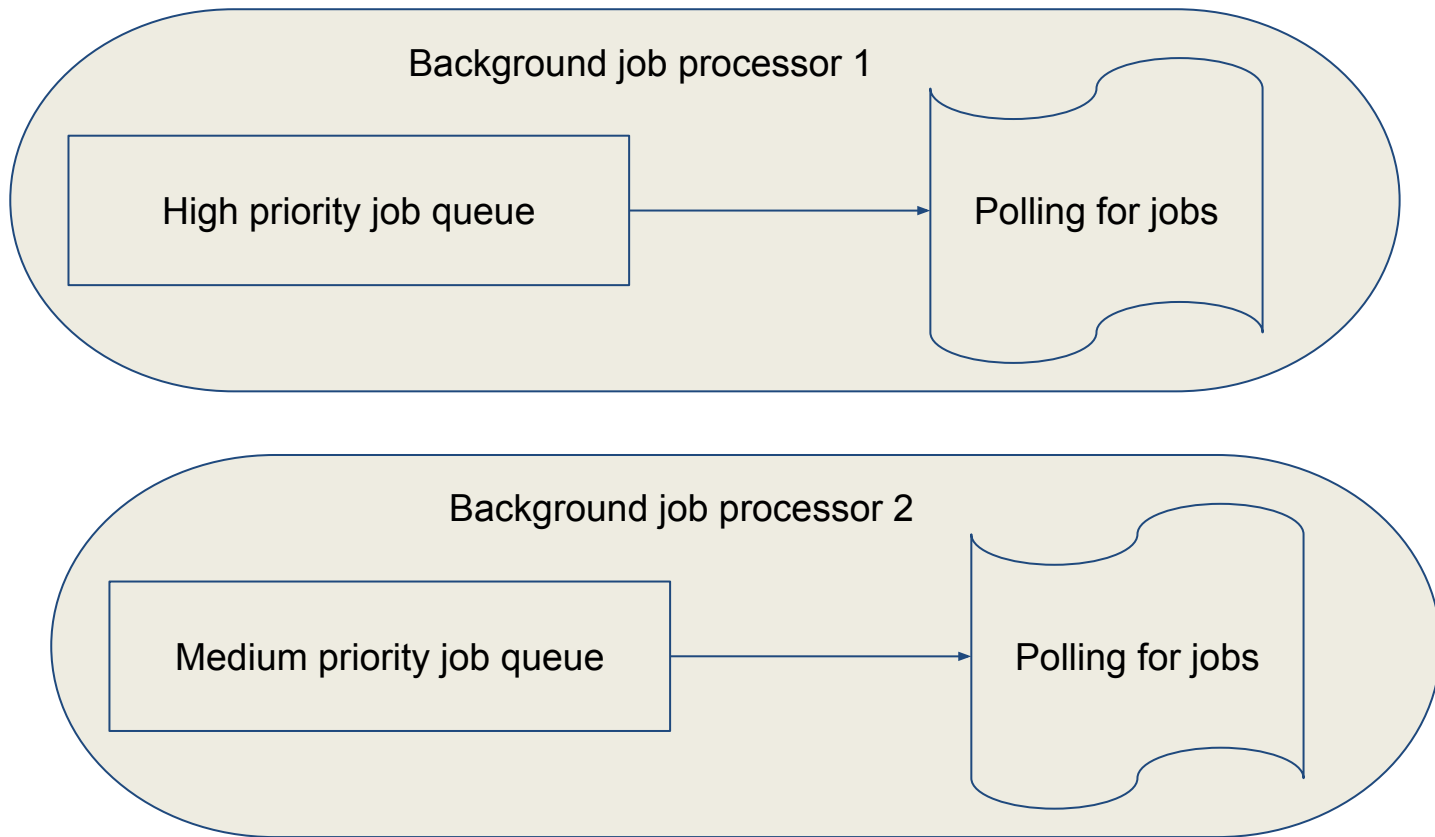

Scenario 2: Problems

- Must have one polling frequency
- Uniform resource allocation
- Difficult root cause identification

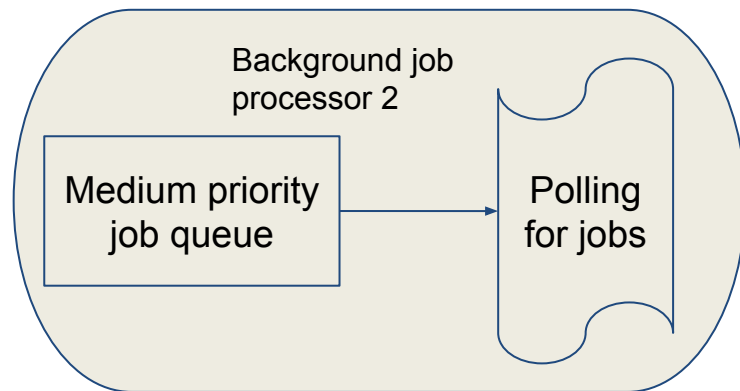

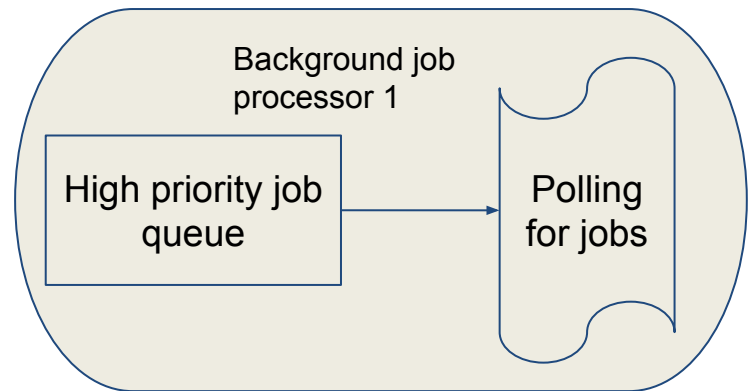

Recipe 2: Separate process per job queue

Recipe 2: Improvements

- Better resource allocation
- Queue-specific polling frequency
- Easier root cause identification
- Easier to have separate datastore per queue

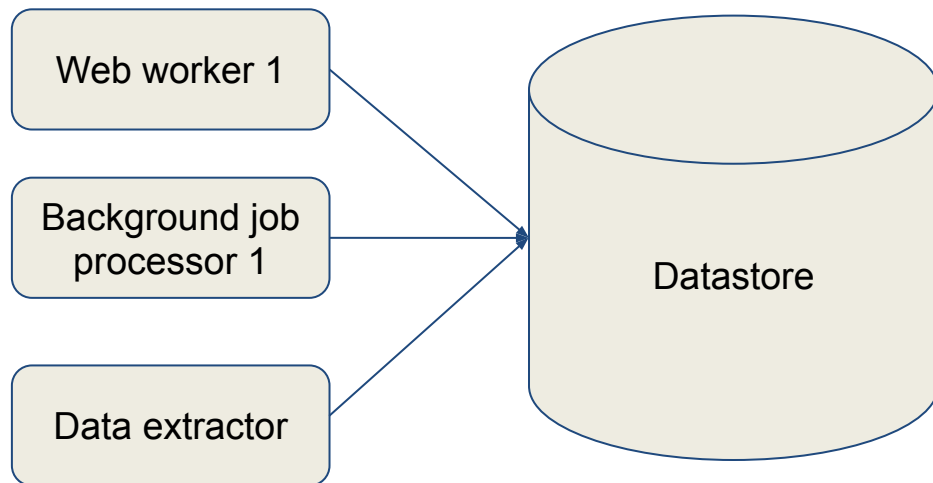

Scenario 3: One datastore and one credential set

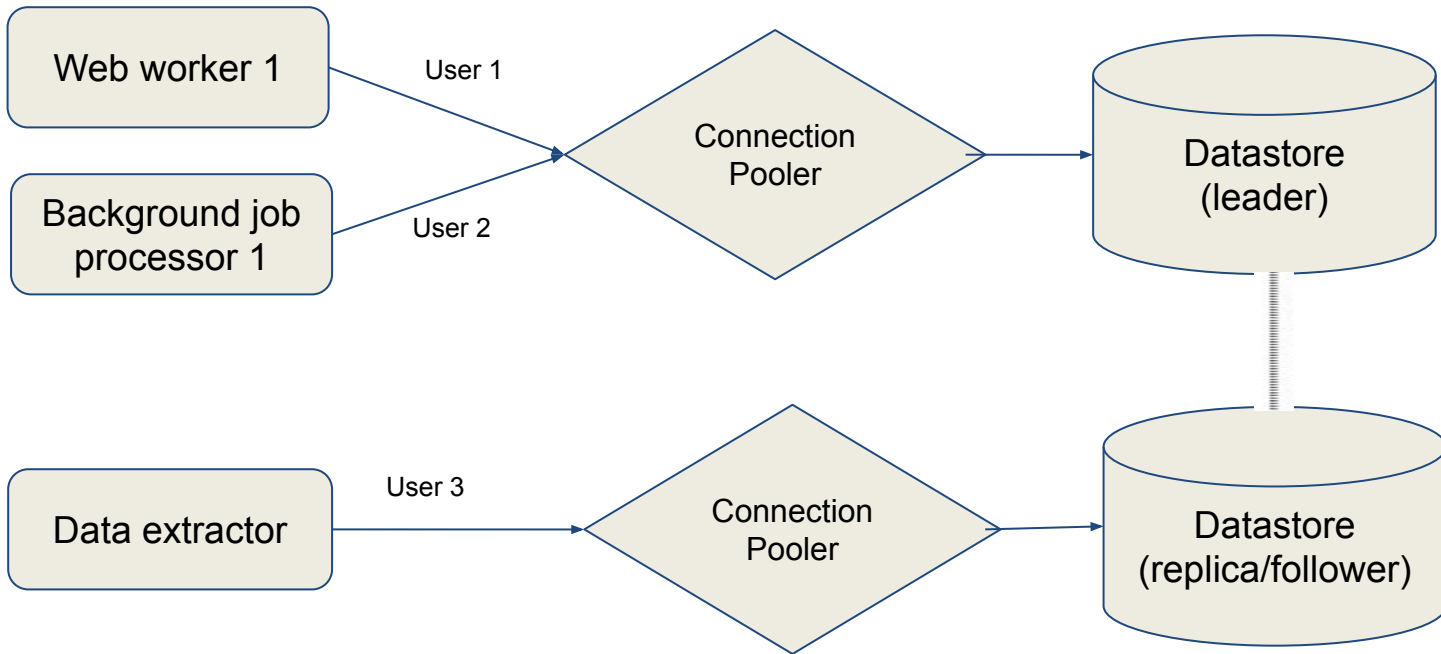

Scenario 3: Problems

- Read spikes can affect write performance and vice versa
- Upgrades are limited
- Datastore logs with login user are difficult to interpret
- Faulty deployments can exhaust connections

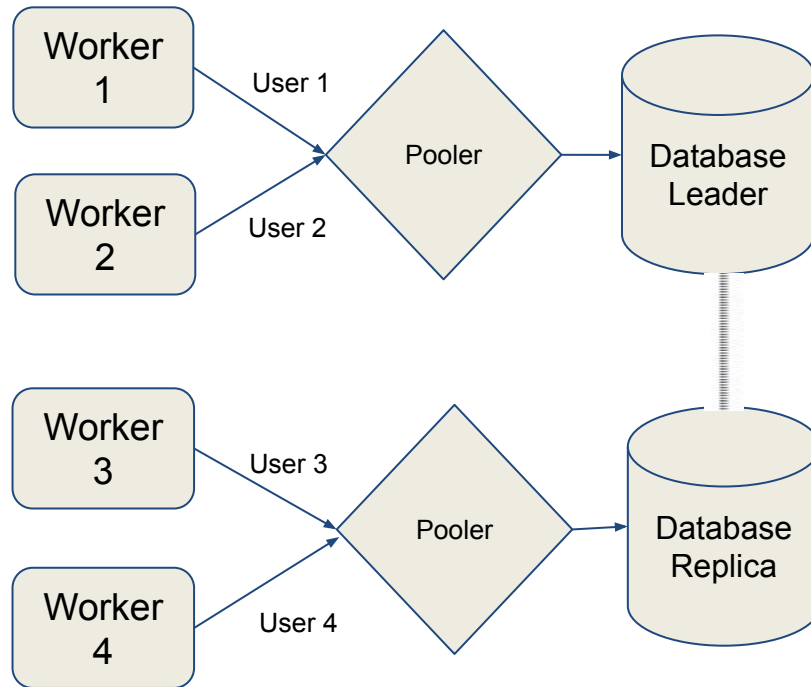

Recipe 3: Poolers, replicas, and multiple users

Recipe 3: Improvements

- Read/write affect each other less
- Connection exhaustion less likely
- Easier tracing query source through datastore logs with username
- Worker-specific data access level

Recipe 4: Improve development workflows

deliveroo

Recipe 5: Improve "Mean Time to Detect" (MTTD)

deliveroo

Recipe 6: Actively know your vendor's limits

deliveroo

Conclusion: You CAN tame the beast!
