Leveraging Semantic Relations in Code and Data to Enhance Taint Analysis of Embedded Systems

Jiaxu Zhao, Yuekang Li, Yanyan Zou*, Zhaohui Liang, Yang Xiao, Yeting Li
Bingwei Peng, Nanyu Zhong, Xinyi Wang, Wei Wang, Wei Huo*

Embedded Systems

- Embedded systems are typically installed on different types of IoT devices and network devices, the number of devices in use is expected to reach **27.1 billion by 2025**[1].
- According to recent statistics[2], **weekly attacks** on IoT devices have **increased by 41% per organization** in the first two months of 2023 compared to 2022.

IPCamera

Firewall

VPN

Router

Switch

NAS

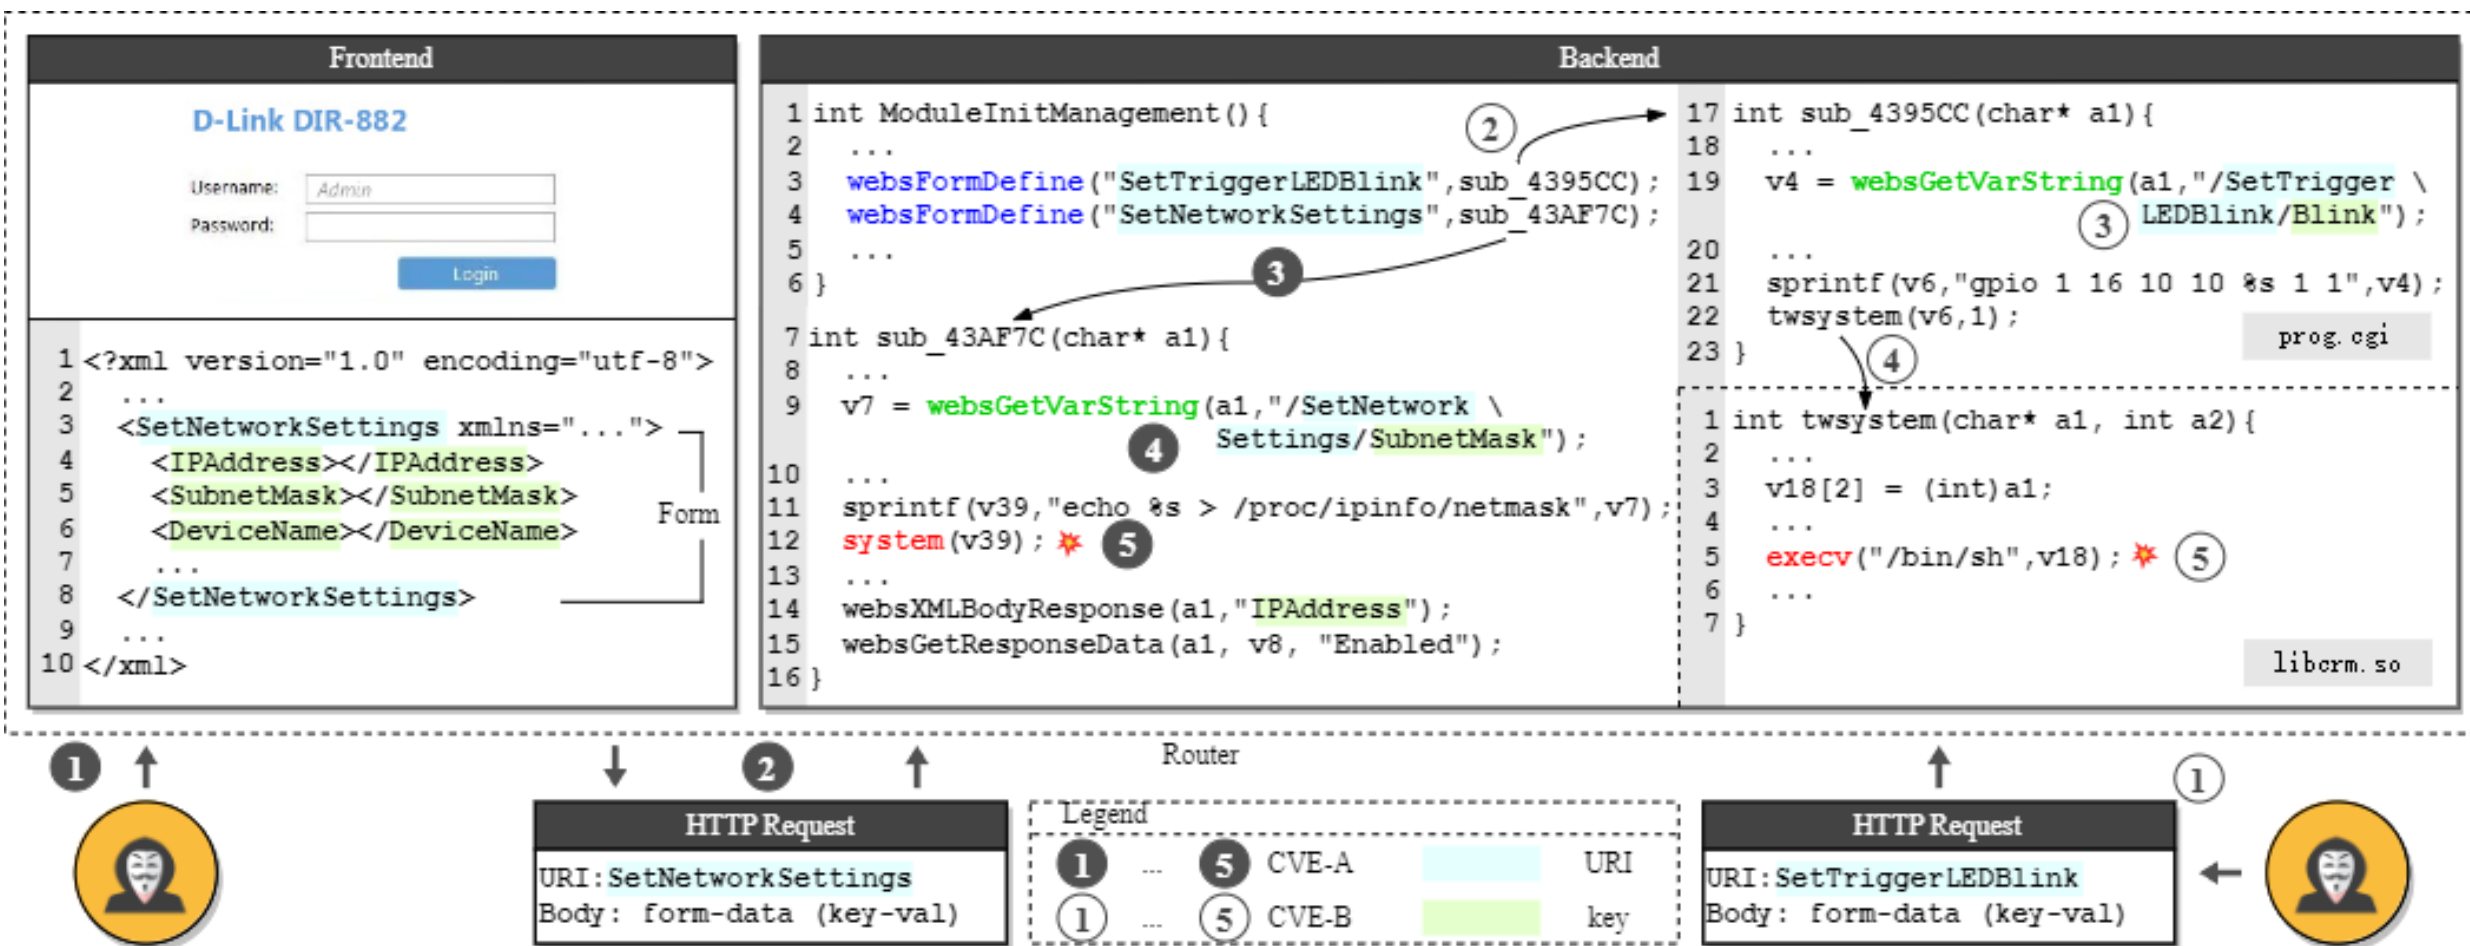

[1] <https://iot-analytics.com/number-connected-iot-devices/>

[2] <https://blog.checkpoint.com/security/the-tipping-point-exploring-the-surge-in-iot-cyberattacks-plaguing-the-education-sector/>

Existing Methods

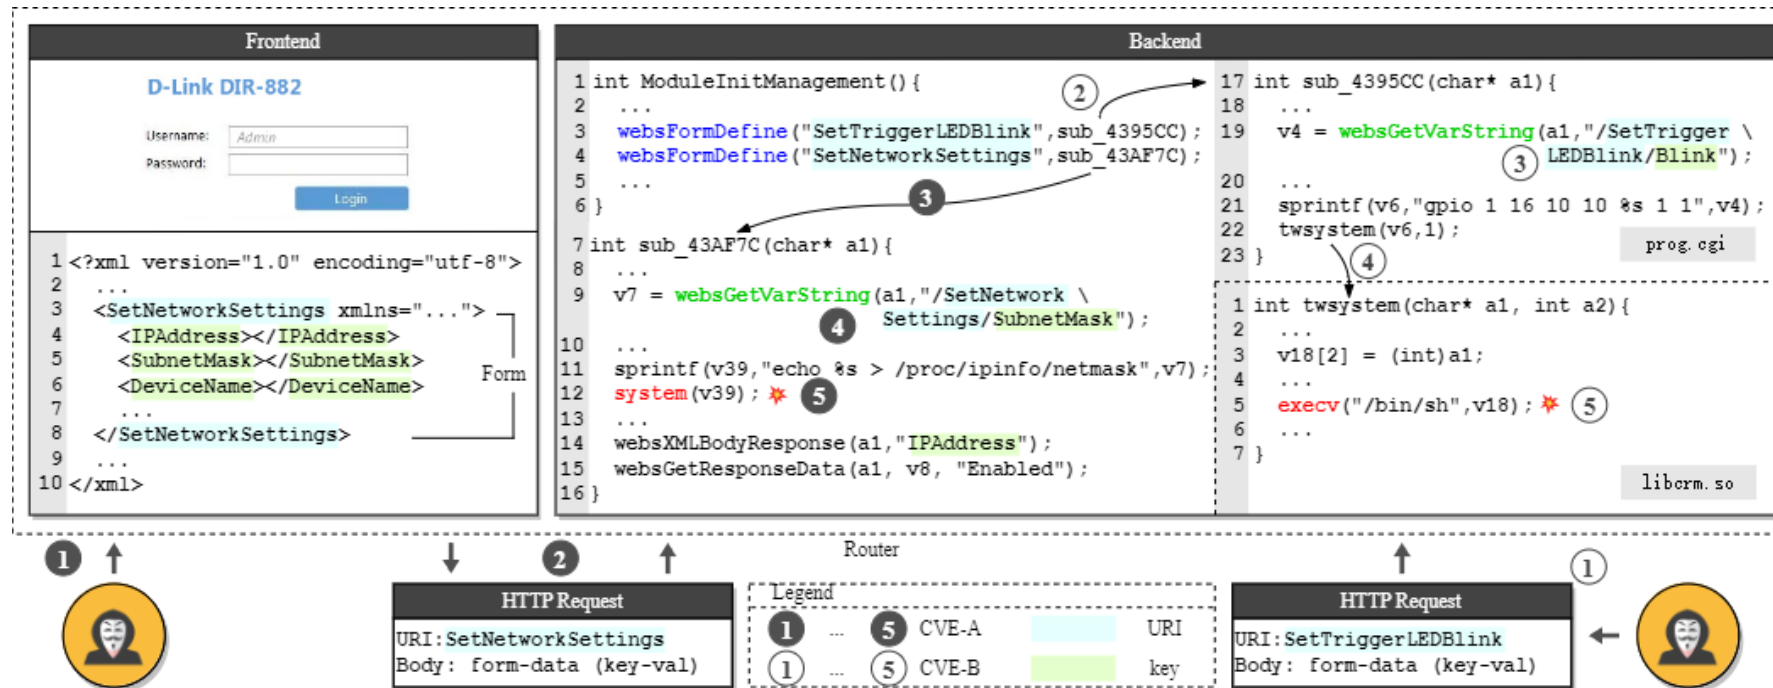

- Dynamic solutions
 - Black-box fuzzing and fuzzing based on emulator
 - Limited by **code coverage** and **simulation success rates**
 - Only focus on **memory-related vulnerabilities**
- Static methods
 - Taint analysis and Symbolic Execution
 - Static analysis is more applicable, but the problem of **false positives and false negatives** still needs to be solved!!!

Motivating Example

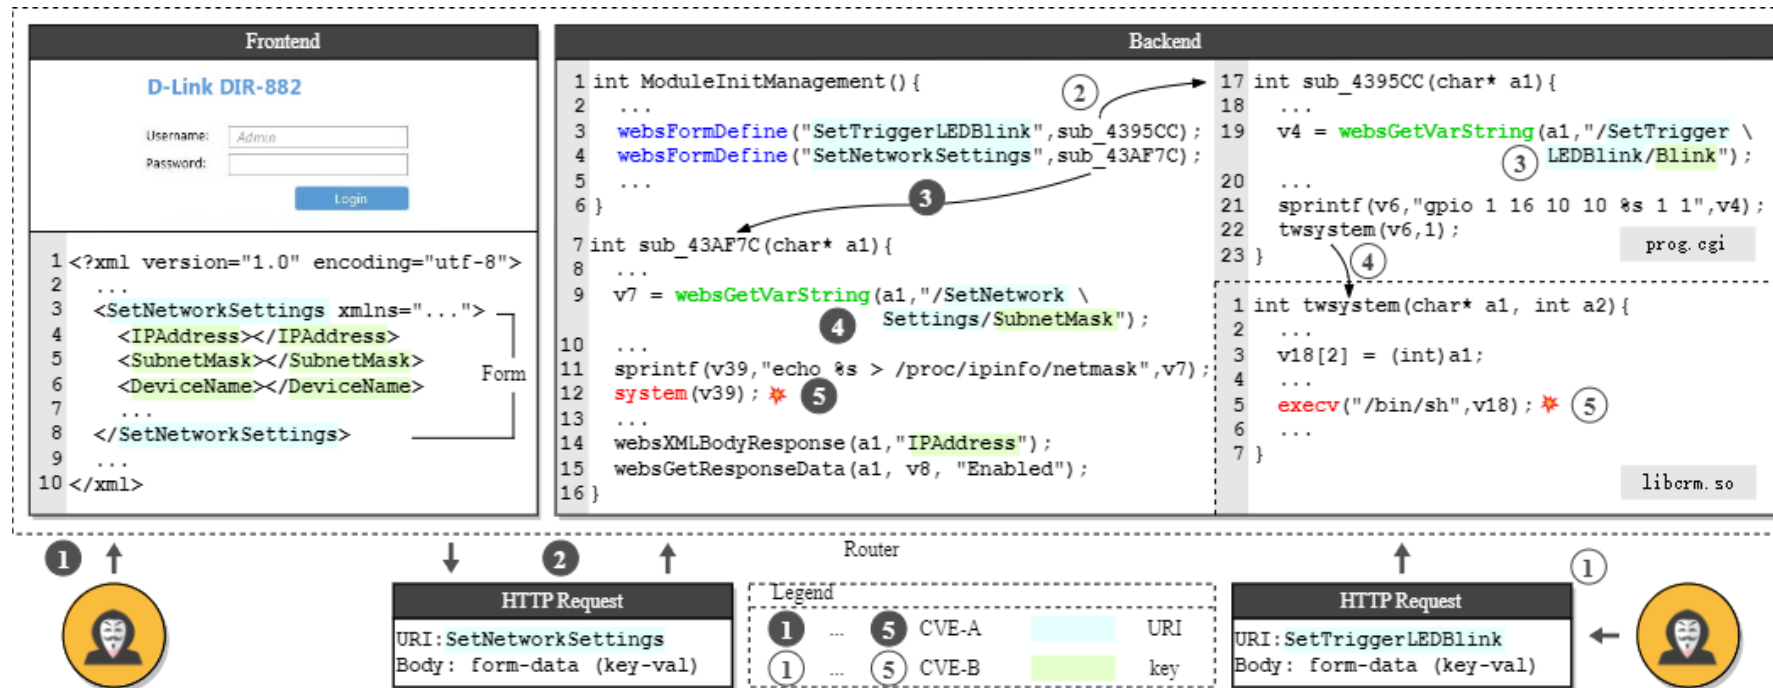

Motivating Example

- SaTC (sec21) fails to find the sources for both CVE-A and CVE-B
 - CVE-A: incomplete redefined rules for extracting source from the frontend
 - CVE-B: lack of support for extracting hidden data

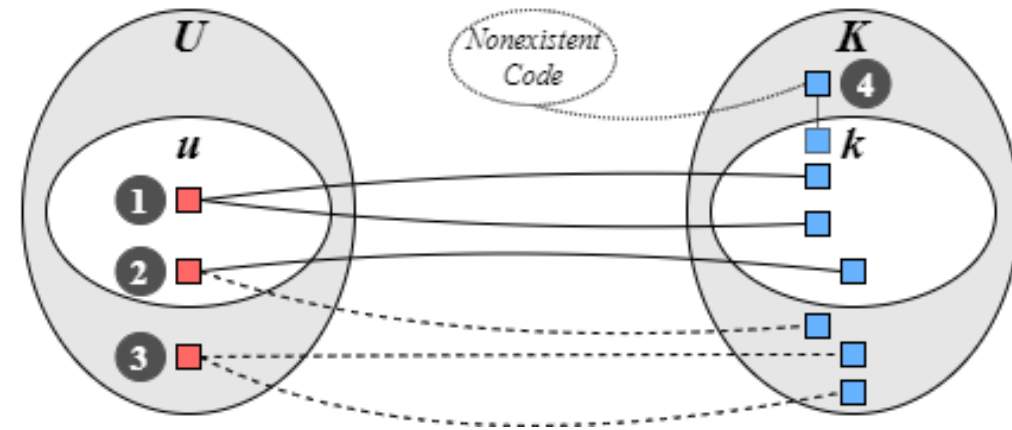

Observation

- User input entries can be categorized as **URIs** or **keys**.
- Some URIs and keys are **non-hidden** and some are **hidden**.
- Different URIs and keys shares **same handing codes**.

Findings

- Finding 1: User input entries can be categorized as **URIs** or **keys**. Identifying their corresponding handling codes and relationships can help to identify both hidden and non-hidden user input entries and locate the taint sources.
- relationships between URIs and keys
 - Non-hidden URIs and non-hidden keys
 - Non-hidden URIs and hidden keys
 - hidden URIs and hidden keys
 - the keys do not have any related URIs

Findings

- Finding 1: User input entries can be categorized as URIs or keys. Identifying their corresponding handling codes and relationships can help to identify both hidden and non-hidden user input entries and locate the taint sources.
- Challenge 1: the key problem in converting it into methodology is how to identify the backend URI and key handling codes.
- Intuitively, we can conclude some patterns to identify these codes to address this challenge.
- Some non-hidden URIs and keys —> corresponding handling codes —> other hidden and non-hidden URIs and keys

Findings

- the semantic information in the backend code can facilitate more precise pattern-based static analysis, such as inferring the purpose of a function.
 - key *time* → key handling function *websGetVar* ✓
 - key *time* → key handling function *strcmp* ✗

```
// non-hidden key
time_interval = websGetVar(wp, "time", "00:00-06:30");
// hidden key
close type = websGetVar(wp, "ledCloseType", "allclose");
if(!strcmp(old_sched_led_type, "time", 4) && !strcmp(sched_led_type,
"close", 5)) {
```

- Challenge 2: Effectively perform **semantic-based analysis** and combine it with pattern-based analysis is another challenge.

Findings

- Finding 2: Due to **the better understanding of code semantics** provided by LLM and **the differences in false positive sources between LLM-aided analysis and pattern-based static analysis**, LLM-aided analysis effectively enhances the identification of more accurate sources.
- False positives in pattern-based static analysis are caused by **code patterns**, while false positives in LLM-aided analysis are due to **misleading code semantics**, such as symbolic data.

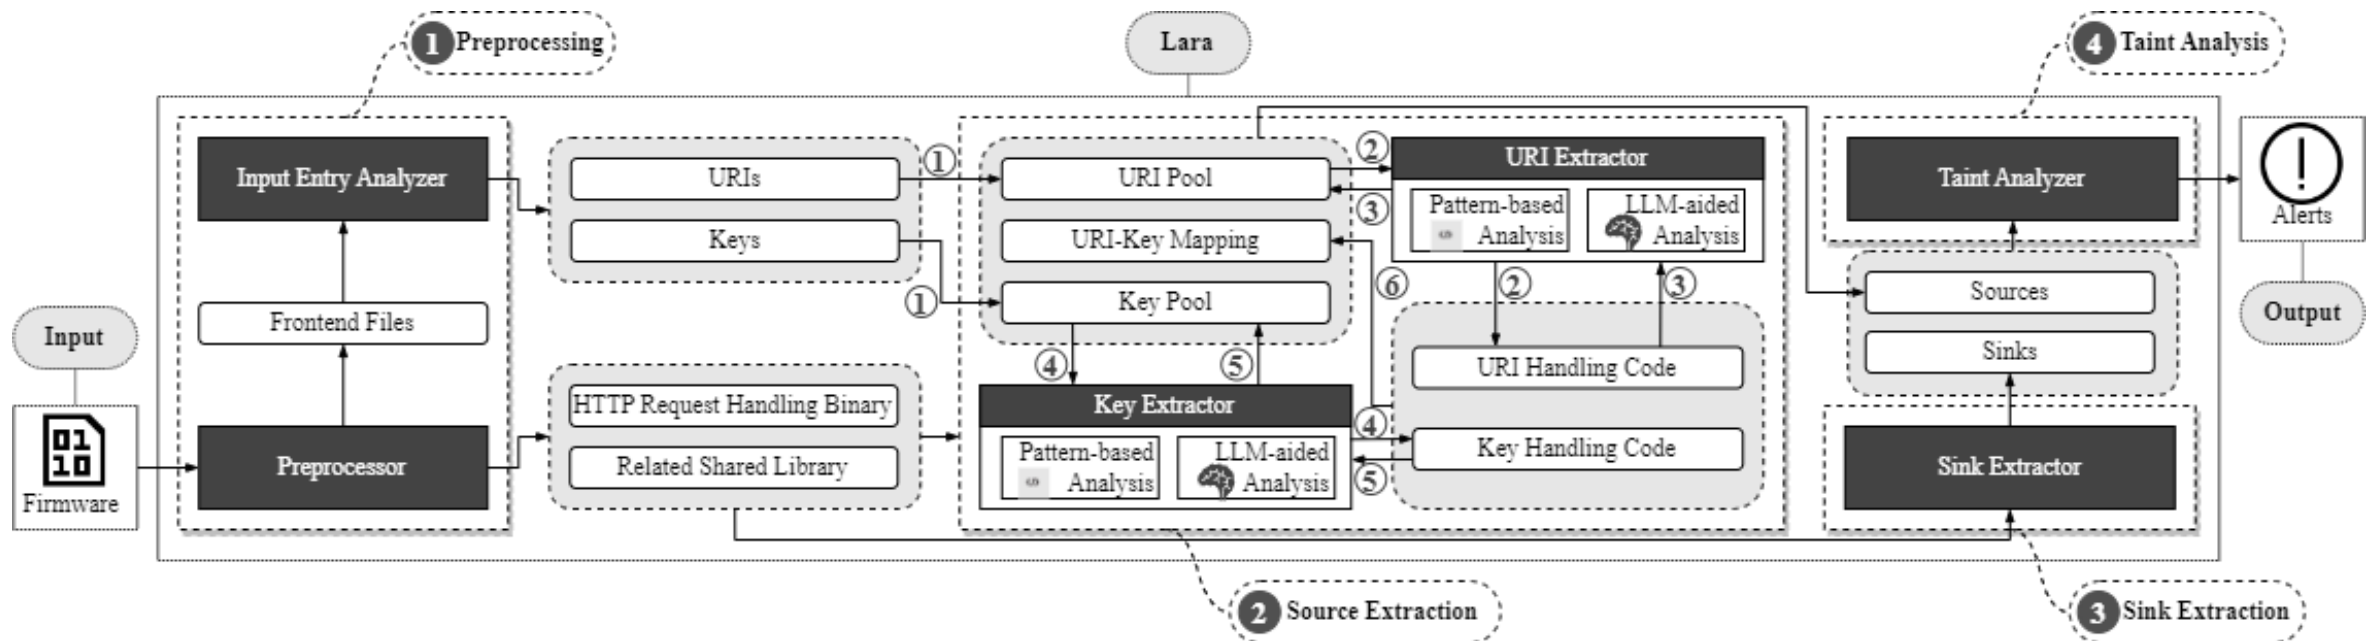

- Pattern-based FP: websXMLBodyResponse
- LLM-aided FP: websGetResponseData

The image shows a screenshot of a D-Link DIR-882 login page on the left. The page has a 'Username' field with 'Admin' entered, a 'Password' field, and a 'Login' button. Below the page is an XML response snippet where the `<IPAddress></IPAddress>` tag is highlighted with a red box and labeled 'Form'. To the right is a C code snippet. Line 4 contains `websFormDefine("SetNetworkSettings", sub_43AF7C);` with a circled '3' and an arrow pointing to the XML response. Line 9 contains `v7 = websGetVarString(a1, "/SetNetwork \ Settings/SubnetMask");` with a circled '4'. Line 12 contains `system(v39);` with a circled '5'. Lines 14-15 contain `websXMLBodyResponse(a1, "IPAddress");` and `websGetResponseData(a1, v8, "Enabled");` which are both highlighted with a red box. A circled '2' is at the top right of the code block with an arrow pointing to the `websFormDefine` call on line 4.

```
1 int ModuleInitManagement() {
2   ...
3   websFormDefine("SetTriggerLEDBlink", sub_4395CC);
4   websFormDefine("SetNetworkSettings", sub_43AF7C);
5   ...
6 }
7 int sub_43AF7C(char* a1) {
8   ...
9   v7 = websGetVarString(a1, "/SetNetwork \
10  Settings/SubnetMask");
11   sprintf(v39, "echo %s > /proc/ipinfo/netmask", v7);
12   system(v39);
13   ...
14   websXMLBodyResponse(a1, "IPAddress");
15   websGetResponseData(a1, v8, "Enabled");
16 }
```

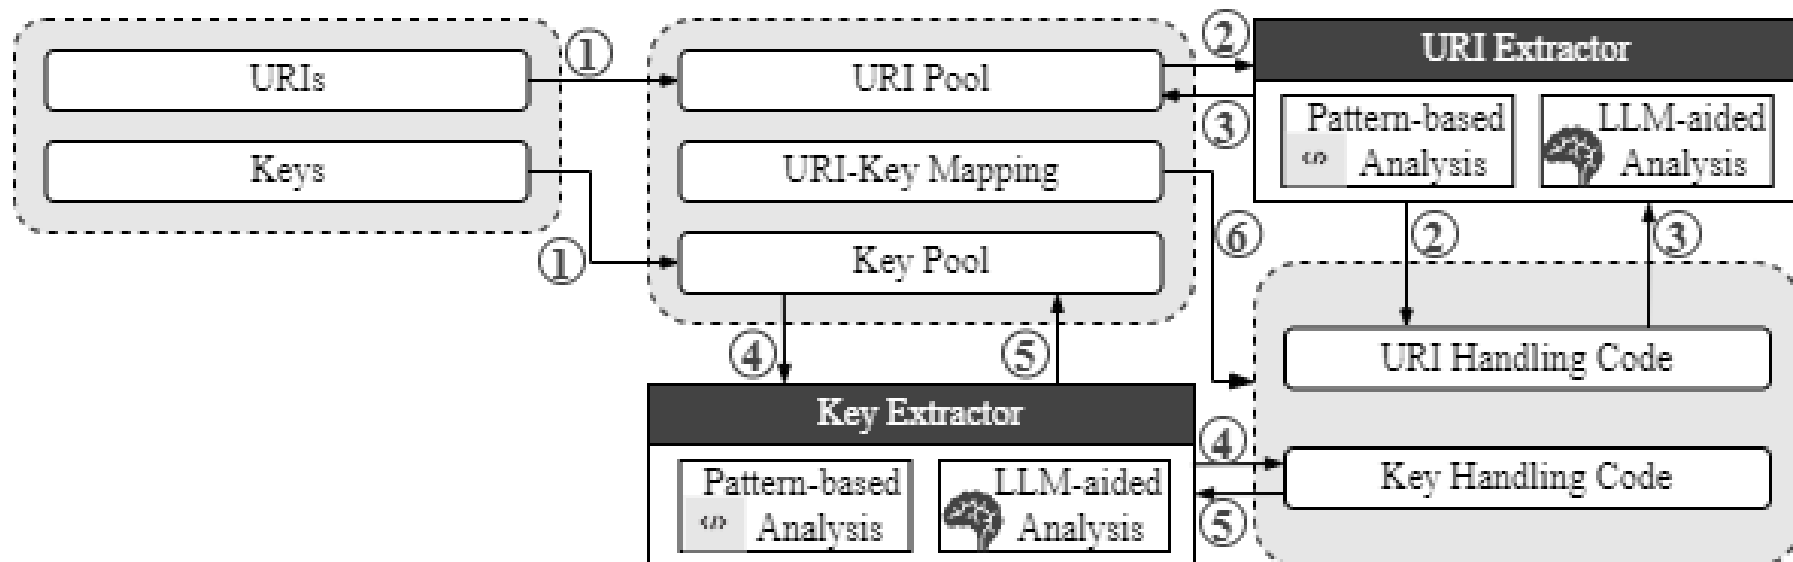

Lara | Architecture

- **Source Extraction:** Pattern-based Static Analysis && LLM-aided Analysis
- **Sink Extraction**
- **Taint Analysis**

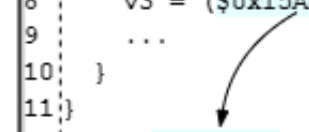

Lara | Source Extraction

- ①-②: use the URIs extracted from the frontend to **identify the URI handling code**
- ③: enrich the URI pool with **URIs not included or found in the front-end**
- ①-④: uses the keys extracted from the frontend to **identify the key handling code**
- ⑤: enrich the key pool with **keys not included or found in the front-end**
- ⑥: uses the mapping between URIs and keys to **filter out unreachable key handling code**

Lara | Pattern-based Static Analysis

- We studied the backend programs of mainstream firmware and found that **the code to bind URIs with URI handling codes** can be categorized into three types.
- URI → URI binding code → URIs and URI handling functions

URI Binding Code Type 1 - Registration Function	URI Binding Code Type 2 - Constant Data	URI Binding Code Type 3 - Process Creation
<pre>1 int formDefineFirewall(){ 2 websFormDefine("BasicSettings",sub_44FFD0); 3 websFormDefine("portForward",sub_44EFF0); 4 websAspDefine("checkBridgeModeASP",sub_448F14); 5 }</pre>	<pre>6 int HandleSocket(){ 7 for(j=0; ; ++j){ 8 v3 = (\$0x15AD80)[2*j]; 9 ... 10 } 11 } 12 .data:0x15AD80 DCD aGetStr // URI:getstr 13 .data:0x15AD84 DCD sub_AB16C // handling func 14 ... 15 .data:0x15BDD8 DCD awifiCgi // URI:wifi.cgi 16 .data:0x15BDDC DCD sub_82A64 // handling func 17 ... 18 .data:0x15C144 ALIGN 0x10</pre> 	<pre>19 int websCgiHandler(char *a1){ 20 cgiName = websGetCgiName(a1); // cgiName:uri.cgi 21 v36 = websLaunchCgi(...,cgiName,data,...); 22 } 23 int websLaunchCgi(...){ 24 v24 = fork(); 25 if(!v24){ 26 if(execve(cgiName,a2,...)!=-1) 27 ... 28 }</pre>

Lara | Pattern-based Static Analysis

- When the program parses the HTTP request body, the function that handles these data extracts the value corresponding to the key.
- To make sure the extracted key is associated with the HTTP request, Lara checks if the parameters of the key handling function and the URI handling function have an intersection.
- key → key handling function
→ corresponding keys for every URI

```
Key Handling Code
1 int formSetSchedLed(wp,path,query) {
2     // non-hidden key
3     time_interval = websGetVar(wp,"time","00:00-06:30");
4     // hidden key
5     close type = websGetVar(wp,"ledCloseType","allclose");
6     if(!strcmp(old_sched_led_type,"time",4)&&!strcmp(sched_led_type,
7         "close",5)){
8         ResponseResultString = GetResponseResultString(v6);
9         ...
10        respCgiSendResp(v6,v7,"PWD_password",query);
11    }
12    get_mib_2cJSONString(root,"config","w15g.bss.wps.basic_have_config",
13        &wifi_buf_entry);
14    ...
15    return sub_1BB34("PWD_password",query);
16 }
↳ Pattern-based Analysis → {websGetVar, respCgiSendResp, strcmp, sub_1BB34}
```

Lara | LLM-aided Analysis

- We designed **corresponding LLM interaction models** for extracting URIs and keys based on the **LMQL**(PLDI2023), enabling LLM-aided analysis to produce valid results without manual interactions.
- Prompt Design
- Merge Operation

```
LLM interaction model for extracting URI Registration Function
1 query:
2 [CoT Prompts]
3 f = Locate_function(URI_reference_address)
4 "Analyze the function f pseudocode and identify each called function"
5 funcs = []
6 "[FUNCS]"
7 funcs += (FUNCS.list())
8 result = []
9 for func in funcs:
10 "Whether the function func is with registration functionality?"
11 "[A2]"
12 if A2 == "YES":
13 result.append(func)
14 from "GPT-3"
15 where
16 FUNCS over OPTIONS.split(",") and
17 STOPS AT(A2, "YES")OR STOPS AT(A2, "NO")
```

Lara | LLM-aided Analysis

- LLM-aided analysis can identify more URI registration functions for URI binding code type I.
- LLM contributes more on reducing FPs when extracting key handling functions.

```
URI Binding Code Type 1 - Registration Function
1 int formDefineFirewall() {
2     websFormDefine("BasicSettings", sub_44FFD0);
3     websFormDefine("portForward", sub_44EFF0);
4     websAspDefine("checkBridgeModeASP", sub_448F14);
5 }
```

Pattern-based Analysis	→ {websFromDefine}
LLM-aided Analysis	→ {websFromDefine, websAspDefine}
Composite Result	→ {websFromDefine, websAspDefine}

```
Key Handling Code
1 int formSetSchedLed(wp, path, query) {
2     // non-hidden key
3     time_interval = websGetVar(wp, "time", "00:00-06:30");
4     // hidden key
5     close_type = websGetVar(wp, "ledCloseType", "allclose");
6     if(!strcmp(old_sched_led_type, "time", 4) && !strcmp(sched_led_type,
7         "close", 5)) {
8         ResponseResultString = GetResponseResultString(v6);
9         ...
10        respCgiSendResp(v6, v7, "PWD_password", query);
11    }
12    get_mib_2cJSONString(root, "config", "w15g.bss.wps.basic_have_config",
13        &wifi_buf_entry);
14    ...
15    return sub_1BB34("PWD_password", query);
16 }
```

Pattern-based Analysis	→ {websGetVar, respCgiSendResp, strcmp, sub_1BB34}
LLM-aided Analysis	→ {websGetVar, get_mib_2cJSONString, GetResponseResultString}
Composite Result	→ {websGetVar}

Lara | Sink Extraction

- **Function-call sinks**

- standard library function, like strcpy(), system().
- **wrapper function**, like save_encrypted_data() from shared libraries wraps popen().

- **Non-function-call sinks**

- direct variable operations, which may affect the contents of variable values, the positions of array reads, the number of controlled loop iterations, and so on.

```
1 | int save_encrypted_data(char *a1, char *a2){  
2 |     memset(s, 0, 0x200);  
3 |     snprintf(s, 0x200, "echo -n %s | openssl ... -out %s",  
   | ↪ a1, a2);  
4 |     return popen(s, "r");  
5 | }
```

Lara | Taint Analysis

- **Source:** taint source is the variable to which the value corresponding to the key is assigned. This variable can be **an argument or a return value of the function**.
- **Taint Analysis:** Taint analysis begins at the URI handling function where the processing of the HTTP request body begins. And the taint analysis engine is based on **IDAPython**, including **intra-function and inter-function propagation**.
- **Vulnerability Detection:** Non-function-call sink models and dangerous standard library function sink models are predefined. Wrapper function models are extended based on the results of wrapper function extraction. Lara checks **constraints** when tainted data reaches a sink.

Evaluation

- **RQ1:** How is the performance of Lara comparing with the state-of-the-art tools?
- **RQ2:** How effective each part of Lara is for discovering vulnerabilities?
- **RQ3:** Can Lara discover previously unknown real-world vulnerabilities in firmware?

Evaluation | Dataset

- **Firmware Dataset:**

The dataset comprises **203 firmware samples from 21 vendors, including 10 different device types**, covering 80 Routers, 37 APs, 20 Switches, 19 IPCameras, 17 Firewalls, 11 Range Extenders, 6 VPNs, 6 Modems, 4 Bridges, 3 NAS.

- **Known Vulnerability Dataset**

To have **a fair ground truth**, we collected all known buffer overflow vulnerabilities and command injection vulnerabilities that exist in these firmware samples from CVE records, while filtering out vulnerabilities without detailed information. we totally collected **646 known vulnerabilities**.

Evaluation | Baselines

- Karonte focuses on vulnerabilities caused by interactions between multiple binaries.
- SaTC uses sources extracted from the frontend, and sinks are predefined functions.
- EmTaint utilizes on-demand alias analysis to enhance taint tracking.
- various variants of Lara.

Experiment Mode	Key-sensitive Taint Analysis	Key-pattern Analysis	URI-pattern Analysis	LLM-aided Analysis	Sink Extraction
LARA-Sink	✓	✗	✗	✗	✓
LARA-Key	✓	✓	✗	✗	✗
LARA-Pattern	✓	✓	✓	✗	✗
LARA-LLM	✓	✗	✗	✓	✗
LARA-Combined	✓	✓	✓	✓	✗
LARA	✓	✓	✓	✓	✓

RQ1: Comparison with the SOTA tools

- Compared with SaTC, Lara detected **556 more vulnerabilities** and incurred **65.5% less time overhead**.
- Compared with Karonte, Lara detected **602 more vulnerabilities** and incurred **63.1% less time overhead**.

RQ1: Comparison with the SOTA tools

- Lara extracted a total of 27,781 URIs and 102,905 keys from the dataset with a precision of **99.8%** and **99.7%**, including **9,299 hidden URIs** and **15,411 hidden keys**.
- SaTC identified 5,201 URIs and 34,081 keys with a precision of **83.2%** and **52.7%**.

Tools	Vulnerability Detection				URI Registration Fun.			URI			Key Handling Fun.			Key		
	#Alert	TP	Prec.	Reca.	#	TP	Prec.	#	TP	Prec.	#	TP	Prec.	#	TP	Prec.

RQ1: Comparison with the SOTA tools

- With more sources and sinks from Lara, EmTaint could detect **245 more vulnerabilities**.

Tools		TP	FP	FN	Prec.	Reca.
EMTAINT	Prototype	14	275	632	4.8%	2.2%
EMTAINT+LARA	EnhanceI	212	162	434	56.7%	32.8%
	EnhanceII	259	168	387	60.7%	40.1%
EMTAINT+SATC	EnhanceI	45	226	601	16.6%	7.0%
	EnhanceII	47	231	599	16.9%	7.3%

- FP Analysis for Lara: **105 false positives** occurred due to LARA disregarding critical key operations between the source and sink, incorrect identification of sinks leads to 37 false positives.
- FN Analysis for Lara: **8 vulnerabilities** were not detected due to either the complex inter-process communication (IPC) method or problems with the disassembly engines itself.

RQ2: Ablation Study

- Contribution of Source Extraction.
 - Lara-Combined (with the same sink) detected **additional 422 vulnerabilities**, thus achieving a 58.8% and 65.3% improvement in precision and recall, respectively.
 - This can be attributed to the fact that Lara-Combined extracted **23,385 more URIs** and **84,638 more keys** than SaTC while maintaining a higher precision rate.

Tools	Vulnerability Detection				URI Registration Fun.			URI			Key Handling Fun.			Key

LARA	780	638	81.8%	98.8%	132	122	92.4%	27,781	27,714	99.8%	388	383	98.7%	102,905	102,597	99.7%

RQ2: Ablation Study

- Contribution of LLM-aided Analysis
 - LLM-aided analysis contributes more on reducing the FPs than reducing the FNs.
 - Compared with Lara-Pattern, Lara-Combined reduces the FPR of vulnerability detection by **10.9%**, the FPR of URI registration function identification by **57.9%**, the FPR of key handling function identification by **61.6%**, and the FPR of keys by **33.9%**.
 - Meanwhile, Lara-Combined reduces the FNs by detecting **6 more vulnerabilities**, **52 more URI registration functions**, **2,745 more URIs**, and **164 more keys**.

Tools	Vulnerability Detection				URI Registration Fun.			URI			Key Handling Fun.			Key

RQ2: Ablation Study

- Contribution of Sink Extraction
 - Lara-Sink has identified **86 additional vulnerabilities** in comparison to SaTC.
 - Lara has identified **134 more vulnerabilities** compared to Lara-Combined.

Tools	Vulnerability Detection				URI Registration Fun.			URI			Key Handling Fun.			Key		
	#Alert	TP	Prec.	Reca.	#	TP	Prec.	#	TP	Prec.	#	TP	Prec.	#	TP	Prec.

RQ3: Real-world Vulnerabilities

- Lara uncovered **245 previously unknown vulnerabilities**, and 162 of them have been assigned CVE IDs following responsible disclosure.
- 32 were due to hidden data, and 52 were caused by dangerous wrapper functions.

Vendor	#Series	#0-Day Vuln			#Hidden	#Wrapper Func.
		LARA	SATC	KARONTE		
Tenda	8	81	26	1	5	3
TOTOLink	16	48	0	0	6	23
DLink	4	33	0	0	13	16
H3C	3	21	0	0	4	0
TRENDnet	5	15	7	4	1	3
Linksys	3	13	3	5	2	2
QNAP	3	12	0	0	0	0
Draytek	4	9	0	0	1	5
TPLink	4	4	0	0	0	0
ASUS	3	3	0	1	0	0
Cisco	2	3	0	0	0	0
Zavio	1	2	0	0	0	0
NetGear	1	1	0	0	0	0
Total	57	245	36	11	32	52

Summary

- Lara can capture sources with low false positive and false negative rates and thus can detect more vulnerabilities.
- Lara can significantly outperform the state-of-the-art IoT static analysis techniques by detecting more vulnerabilities with fewer false positives.
- We discovered 245 0-day vulnerabilities in 57 devices from 13 vendors, 162 of them have been assigned CVE IDs.

Q&A

Semantic Relations: Code and Code, Code and Data, Data and Data

More sources and more sinks make more vulnerabilities!

Thanks for your listening!
